Dear Colleagues:

On behalf of California's Office of Statewide Health Planning and Development (OSHPD), I am pleased to preface our latest report on the outcomes of care in California's hospitals. These outcome studies, mandated by legislation (Assembly Bill 524) signed by Governor Wilson in 1991, are based on data routinely abstracted from hospital medical records and reported to OSHPD for every patient discharged from a California hospital.

This third report on heart attack mortality rates expands and improves upon earlier studies using a larger body of data, refined risk-adjustment methods, and linkage to death certificate information. The study, therefore, represents an important contribution in efforts to evaluate the quality of health care provided throughout the state.

OSHPD had overall responsibility for the project. Andra Zach, R.R.A., M.P.A., served as coordinator. The statistical studies were performed by a distinguished team of researchers from the University of California medical schools at Davis and San Francisco, led by Patrick S. Romano, M.D., M.P.H., and Harold S. Luft, Ph.D. In addition, the Project had the benefit of valuable suggestions from several advisory bodies: the California Health Policy and Data Advisory Commission; its technical advisory committee, made up of representatives of the health services research, hospital, nursing, medical, health information and consumer communities; and from a panel of clinical experts in the field of cardiovascular disease.

OSHPD's primary goal in conducting such studies on outcomes of care, and reporting the results, is to improve the quality of hospital care available to all California citizens. The report provides hospitals with systematic information about their patient care results in comparison to other facilities, and encourages them to examine their processes of care to determine those which result in the best outcomes.

The AB 524 legislation responded to needs expressed by health care purchasers, providers and consumers to have publicly available information that objectively compares hospital performance in patient care. The legislation called for selection of medical, surgical, and obstetrical conditions for study of outcomes of hospital care. The first conditions selected were heart attack (acute myocardial infarction), back surgery (cervical and lumbar disk excisions), and maternal outcomes of obstetrical care (vaginal and cesarean deliveries). Several reports related to these studies have already been published. A study on the outcomes of care of hip fractures is in progress.

The Office of Statewide Health Planning and Development has made a long-term commitment to provide public information describing the quality of care delivered in California hospitals and, eventually, in other settings of care as well. With the assistance of its advisory bodies and colleagues in the health care community, the Office seeks continued improvements in data collection and analytical methods so as to enhance our ability to evaluate the performance of California's health care institutions.

The Office welcomes your comments and suggestions regarding these reports.

Sincerely,

David Werdegar, M.D., M.P.H.  
Director

## Acknowledgments

This report reflects the efforts of the contractors and staff in the Office of Statewide Health Planning and Development. Work was completed under contracts 93-4158 and 94-5321 with the University of California, Davis, and an intercampus agreement between the University of California, Davis (UC Davis), and the University of California, San Francisco (UC San Francisco). Suggestions to the formatting and presentation style of the *User's Guide* were provided under contract with the University of California, Los Angeles (UC Los Angeles).

Andra Zach, R.R.A., M.P.A. had overall responsibility for all aspects of the project, serving as liaison between OSHPD, the research team, and the included hospitals. OSHPD staff conducted the death certificate linkage and had primary responsibility for writing the *User's Guide*.

The contract team at UC Davis was supervised by Patrick S. Romano, M.D. and Julie Rainwater, Ph.D. The contract team at UC San Francisco was led by Harold S. Luft, Ph.D. Dr. Romano had primary responsibility for writing the *Technical Guide*. Dr. Luft and Dr. Romano had primary responsibility for writing materials accompanying the *Detailed Statistical Results*. Drs. Romano, Luft, and Rainwater, had primary responsibility for writing the *Hospital Guide*, with the assistance of Michael Schembri and Ben Chan, M.S.

Ben Chan, M.S. was responsible for most of the data processing and statistical analyses, with the assistance of Dr. Romano. Michael Schembri prepared the table for the *User's Guide* and provided programming for the *Detailed Statistical Results* and the *Hospital Guide*. Hong Zhou, Ph.D. consulted on statistical issues. Linda Remy, Ph.D., and Theodore Clay, M.S., created the study files from the OSHPD discharge data set.

Rebecka Levan, M.P.H., Leah Vriesman, M.H.A., M.B.A. and Gerald Kominsky, Ph.D. of UC Los Angeles provided suggestions for formatting and presentation style of the *User's Guide*.

A number of individuals provided guidance and advice in the design of the study and provided helpful comments on this or previous reports: Edward Hannan, Ph.D., Clifton Bailey, Ph.D., Lisa Iezzoni, M.D., Gregory S. Binns, Ph.D., along with members of the Technical Advisory Committee and the Clinical Panel.

# Report on Heart Attack

*The California Hospital Outcomes Project is an initiative mandated by the State of California, and conducted by the Office of Statewide Health Planning and Development (OSHDP), to develop public reports comparing hospital outcomes for selected conditions treated in hospitals throughout the state.*

*The Report on Heart Attack is intended to encourage all California hospitals to improve their care and give credit to the hospitals that are the leaders. It can also help insurers, employers, and consumers to select hospitals based on quality of care.*

## The California Hospital Outcomes Project

Heart attacks (acute myocardial infarctions or AMIs) were chosen as one of the first conditions to be reported upon by the California Hospital Outcomes Project because they are important, common, and deadly. Every year approximately 40,000 heart attack patients are admitted to 400 California hospitals. More than 5,000 of these persons die.

The mortality rates published in previous heart attack reports have been used in many ways. Hospitals have used their results to evaluate and improve their quality of care. Payers have used the reports to contract with the best hospitals. Consumers have used the reports to make more informed decisions.

The results published in this report are useful because:

- **They have been risk-adjusted.** Patient age, sex, type of heart attack, and chronic diseases were used to adjust for differences in patient risk when calculating hospital mortality rates.
- **They have been validated.** A major validation study involving nearly 1,000 heart attacks at 30 hospitals showed that variations in how hospitals report their data to OSHDP do not significantly affect their risk-adjusted death rates. In general, low-mortality hospitals treat heart attacks more aggressively than high-mortality hospitals.

## Content of the Report on Heart Attack

This is the third report on heart attack. The first report was published in December of 1993 and the second report was published in May of 1996. This year's report includes heart attack cases from 1991 through 1993. Although 1991 and 1992 cases were included in last year's report, results shown in the current report may be different because the methodology has been improved. These improvements include:

- Linking with Vital Statistics records to ascertain deaths occurring outside the hospital.
- Refining certain patient risk-factor definitions based on the findings of the 1996 validation study.
- Using six months of pre-heart attack hospital records to more completely describe patient risk factors.

This year's report consists of five components:

The *User's Guide* (Volume 1) is intended for all those interested in hospital performance including hospital staff, employers, government agencies, health plans, and insurance companies. This volume provides a brief description of the study background and methods. It also contains two tables that display the results for individual hospitals based on heart attacks that occurred between 1991 and 1993.

The *Technical Guide* (Volume 2) is intended for health services researchers, health care providers, and others interested in the statistical methods used to calculate risk-adjusted death rates.

The *Detailed Statistical Results* (Volume 3) contains the numerical results for individual hospitals upon which the classifications in the *User's Guide* are based. In addition, there are tables that aggregate the results to the county level. It also contains a graphical representation of both individual hospital and county-wide results, which can be used to examine annual trends. An electronic version of the tables is available on diskette.

The *Hospital Comment Letters* (Volume 4) is intended to give readers of the *Report on Heart Attack* an appreciation of its strengths and weaknesses from the hospitals' perspectives

The *Hospital Guide* accompanied patient specific information that was sent to each hospital several weeks before the *Report on Heart Attack* was published. Hospitals used this information to prepare their comment letters, which are provided with each volume of the report. More importantly, hospitals and their physicians can use this information to target areas where heart attack care might be improved.

To obtain these documents contact:

Office of Statewide Health Planning and Development  
Data User's Support Group  
818 K Street  
Sacramento, CA 95814  
(916) 322-2814

Documents, excluding the *Hospital Guide*, are available on the internet at <http://www.oshpd.cahwnet.gov>

## Section

# 1

## Using this Volume

---

*This document describes the hospital-specific statistics developed by the California Hospital Outcomes Project and discusses appropriate ways to use these statistics. The statistics are available in two media: as part of this document, which contains one table for each hospital beginning on page 16, or on a computer diskette which contains one record for each hospital and one record for each county. The only difference between the two versions is that the printed version presents numbers that are rounded off to have fewer digits.*

### Relationship to Other Volumes of this Report

The purpose of this volume of the *Report on Heart Attack* is to provide and explain the detailed statistics associated with heart attack (i.e., acute myocardial infarction or AMI) mortality in California hospitals. It also suggests appropriate uses for these detailed data and explains why certain uses would be inappropriate.

The *User's Guide* (Volume 1) describes the data and summarizes the methods used in the analysis of risk-adjusted heart attack mortality. Statistical methods were used to determine whether each hospital's AMI death rate was significantly different from what would be expected by chance. The results, using aggregated 1991-1993 data, are presented in two charts in the *User's Guide*. The first chart classifies each hospital into one of four categories. The second chart displays these risk-adjusted death rates graphically.

The *Technical Guide* (Volume 2) presents a detailed description of the data and risk-adjustment methods. This detailed methodological presentation is intended to allow users and researchers to review and comment on the approaches taken and to encourage improvements in the future.

As required by law, each hospital and its chief of medical staff were sent summaries of their own results and draft copies of the report. All comments submitted in response to the analysis accompany each volume of the report. These responses should be reviewed carefully if the reader is interested in the results for particular hospitals.

### Statistical Significance and Hospital Classification

The threshold of statistical significance used in this report of the California Hospital Outcomes Project is  $p < 0.01$ . This means that a hospital's risk-adjusted mortality rate was considered to be significantly lower or higher than expected if the hospital's observed death rate was more extreme than what

would be expected to occur by chance 1 percent of the time. Even if every hospital provided the same quality of care, chance variation in outcomes would mean that some hospitals would appear to be high outliers and some low outliers. With roughly 400 hospitals in the analysis, 1 percent or four would have higher than expected mortality due just to chance variation. Another four (1 percent) would have lower than expected mortality by chance. If about 8 of the 400 hospitals were actually identified as outliers, one might conclude that none had quality of care problems, since this many outliers would be likely to occur just by chance.

In fact, 47 hospitals were identified as outliers for AMI mortality using Model A and 42 were identified as outliers using Model B. This distribution is inconsistent with the premise that all hospitals have equal quality. Without additional information from medical records, however, it is impossible to tell which of the outliers provided unusually good or poor quality care and which were outliers just due to chance.

A hospital is unlikely to be an outlier several years in a row just by chance. If this occurs, it probably reflects some consistent factors. Outcomes for AMI patients are based on cases admitted between January 1, 1991 and December 1, 1993. Overall mortality is reported as well as mortality for each of the three years separately. AMI outcomes for each year are calculated by applying the overall mortality model (which adjusts for the year of admission) to a single year's cases. Very few hospitals shift from being extreme low outliers in one year to extreme high outliers in the next. However, some hospitals with initially high mortality do improve over time, possibly because of improvements in quality of care. Similarly, some hospitals with initially low mortality appear to deteriorate over time. The graphs presented in this volume display these temporal trends, but the statistical significance of these trends at individual hospitals has not been assessed.

## Section

# 2

## Explanation of the Detailed Results

Hospital specific results are displayed in two ways. The detailed tables give the statistics upon which the summary results shown in the User's Guide are based. The charts present those results graphically.

### The Tables, an Example

TABLE 1: Detailed Statistical Results for Acute Myocardial Infarction Mortality

Healthy County: General Hospital*											
	Statewide Death Rate (%)	Number of Cases Included	Number of Observed Deaths	Number of Expected Deaths	Standard Deviation of Observed Deaths	Observed Death Rate (%)	Expected Death Rate (%)	Risk-Adjusted Death Rate (%)	Risk Adjusted Death Rate:95% Confidence Bounds		Probability This Rate Occurred by Chance
									Lower	Upper	
Model A All Years	14.5	101	11	15.4	3.3	10.9	15.2	10.4	4.3	16.5	0.120
1991	15.1	30	4	5.4	1.9	13.3	17.9	11.2	0.8	21.6	0.324
1992	14.5	26	3	2.9	1.5	11.5	11.3	14.8	0.2	29.3	0.590
1993	13.9	45	4	7.0	2.3	8.9	15.6	7.9	0.0	16.6	0.126
Model B All Years	14.5	100	11	13.1	3.0	11.0	13.1	12.2	5.8	18.6	0.302
1991	15.1	30	4	5.1	1.8	13.3	16.9	11.9	1.3	22.5	0.392
1992	14.5	25	3	3.0	1.4	12.0	12.2	14.3	1.2	27.4	0.646
1993	13.9	45	4	5.0	1.9	8.9	11.1	11.2	0.9	21.4	0.416

Table 1 summarizes the results for a hypothetical hospital. The first column on the left identifies the specific analytic model and the second column identifies the year(s) of data included in the results. The AMI outcome was death within 30 days of admission for the index AMI. Hospitals with no AMI patients in 1991-1993 are not included in this report. Because of specific data limitations described in Chapter Six of the *Technical Guide*, 27 hospitals with AMI patients were excluded from the analysis in one or more of the three study years. An "Excluded" notation indicates that the data from a hospital in this year were excluded.

Observe that AMI results based on both Models A and B are given. These models are explained in general terms in the *Users Guide* and in detail in the *Technical Guide*. Sometimes slightly fewer patients were analyzed under Model B than Model A. This is because some risk factors unique to Model B (e.g., race, insurance status) were unknown for some patients. When this occurred, that patient was omitted from the Model B analysis. The omission of some cases from Model B causes a slight difference between the two models in the overall death rate.

The results are displayed year-by-year as well as for all years combined. For example, the results in a row labeled “1993” include only eligible patients discharged from the hospital for AMI in 1993. The row labeled “All Years” includes all eligible patients in 1991, 1992, and 1993 combined. Some hospitals do not have any AMI patients in a particular year, but do have patients in other years. In this case, the row corresponding to the year in which the hospital had no cases would be blank.

General Hospital in Healthy County, shown in Table 1, is used as an example for the following explanation of hospital-level summary statistics. The county-level tables in this volume include the same variables as the hospital-level tables described.

The Statewide Death Rate (%) is the total number of patients included in the study who died, divided by the total number of patients included in the study, multiplied by 100 to convert this proportion to a percentage. As Table 1 shows, the overall *Statewide Death Rate* for AMI was 14.5 percent.

The line indicating Number of Cases Included tells how many cases from this hospital were included in the models. A general description of patient inclusion and exclusion criteria is in the *User’s Guide*. A detailed description is in the *Technical Guide*, Chapter Three. Cases with missing data for one or more demographic variables included in Model B (such as race or source of payment) are not included in Model B. The overall number of AMI cases at General Hospital was 101 under Model A and 100 under Model B.

The Number of Observed Deaths is the number of patients at a facility who died within 30 days of admission for AMI. The death may have occurred at the index hospital, a transfer hospital, or outside the hospital setting. The full description of the outcome variable is given in Chapter Five of the *Technical Guide*. At General Hospital, the overall *Number of Deaths* in the AMI analysis was 11 under both Model A and Model B.

The Number of Expected Deaths among patients included in the analysis is presented in the next column. The influence of patient characteristics on the risk of death was estimated from the statistical models described in the *Technical Guide*, Chapter Nine. The predicted probability of death was computed for each patient. Summing these probabilities over all patients treated at a hospital gives the predicted number of deaths among those patients. At General Hospital, the *Number of Expected Deaths* was 15.4 using Model A and 13.1 using Model B.

The Standard Deviation of the Observed Deaths is the square root of the sum, over all of the included patients, of each patient’s probability of death ( $p_i$ ) times the probability of survival ( $1-p_i$ ), i.e.,  $\text{SQRT}(\sum p_i(1-p_i))$ . At General Hospital, the *Standard Deviation of Observed Deaths* was 3.3 for all years using Model A and 3.0 for all years using Model B. Note that the standard deviation of the number of expected deaths is very small relative to this quantity because it is based on a statistical model estimated using a far larger sample. Although the standard deviation of the expected number was

calculated, it did not affect the classification of hospital mortality and was therefore not used in the final analysis.

The Observed Death Rate (%) is the number of patients at this hospital who died, divided by the number of patients at this hospital included in the analysis, multiplied by 100 to convert this proportion to a percentage. For example, under Model A at General Hospital, the overall *Observed Death Rate* for AMI was  $(11/101) \times 100$ , or 10.9 percent. Under Model B at General Hospital, it was  $(11/100) \times 100$ , or 11.0 percent.

The Expected Death Rate (%) is the expected number of patients at this hospital who died, divided by the number of patients at this hospital included in the analysis, multiplied by 100 to convert this proportion to a percentage. General Hospital had 101 AMI patients included in Model A. With 15.4 patients expected to die, General Hospital has an *Expected Death Rate* under Model A of 15.2 percent (after rounding).

The Risk-Adjusted Death Rate (%) is derived using a technique known as indirect standardization. It adjusts the observed death rate at the hospital to reflect what the rate would be if the patients were about as ill as "average" patients in the state. The *Risk-Adjusted Death Rate (%)* is calculated as the statewide rate, multiplied by the number of observed deaths at this hospital to the number of expected deaths. This adjusted death rate can be used to compare the performance of different hospitals.

For example, the *Risk-Adjusted Death Rate* using Model A patients is the statewide rate (14.5 percent) times the observed number of deaths, divided by the expected number of deaths. At General Hospital under Model A, only 11 patients died whereas 15.4 were expected to die. For General Hospital, the risk-adjusted death rate is  $14.5\% \times (11/15.4) = 10.4\%$ . Adjusting for its patient mix, General Hospital's risk-adjusted death rate is lower than its observed rate of 10.9 percent.

Note that the expected death rate (15.2 percent) was higher than the statewide rate (14.5 percent). This difference reflects the fact that patients at General Hospital had higher risk, on average, than the statewide population of patients. The risk-adjusted figure of 10.4 percent is an estimate of what the death rate would be at General Hospital if its patients matched the state average in terms of risk.

The Risk-Adjusted 95% Confidence Bounds reflect the level of confidence in the hospital's risk-adjusted death rate. Assuming that the risk model is correct, there is a 95 percent chance that the hospital's true risk-adjusted AMI death rate under Model A falls between the *Lower 95% Confidence Bound* of 4.3 percent and the *Upper 95% Confidence Bound* of 16.5 percent. Please note that this 95% confidence interval differs from the 98% confidence interval shown in the *User's Guide*. A narrower interval, providing 95% confidence rather than 98% confidence, is used in these tables for the benefit of individual hospitals and physician groups that are interested in evaluating their own performance. Wider confidence intervals are used to

identify hospital outliers in the *User's Guide*, because of the large number of hospitals evaluated in the study.

The Probability This Rate Occurred by Chance is a measure of the likelihood that this many or a more extreme number of deaths occurred by chance, given the expected number of deaths from the risk-adjustment model. If the observed number of deaths is less than or equal to the expected number, a *lower p-value* is computed. If the observed number of deaths is more than the expected number, an *upper p-value* is computed.

The lower p-value is the probability of the observed number of deaths or fewer. The lower p-value represents a "test" of whether this hospital has systematically **better** outcomes than expected based on its patients' risk characteristics. A lower p-value of less than 0.05 indicates that there would be less than a 1 in 20 chance of this hospital having this few or fewer deaths, given its mix of patients, if quality of care were average.

The upper p-value is the probability of the observed number of deaths or more. The upper p-value represents a "test" of whether this hospital has systematically **worse** outcomes than expected based on its patients' risk characteristics. An upper p-value of less than 0.05 indicates that there would be less than a 1 in 20 chance of this hospital having this many or more deaths, given its mix of patients, if quality of care were average.

Because General Hospital had fewer deaths than expected in Model A, the lower p-value of 0.120 was used. Thus, in this hospital with 101 patients (and 15.4 expected deaths, based on Model A risk factors), the probability of observing 11 or fewer deaths due to chance alone is about 1 in 9 -- a finding quite consistent with chance variability. Such a finding provides little evidence that General Hospital's outcomes differ systematically from the statewide average.

A very small p-value of, 0.01 (1/100) for example, means that one would expect to observe so few (if a lower p-value) or so many (if an upper p-value) deaths only 1 time in 100, by chance. A more likely explanation for such an extreme finding would be systematic differences in quality of care or coding of discharge abstracts.

The classification of hospitals into one of four categories, based on all three years of data, (as shown in the *Users Guide*) is based on a p-value of 0.01. Hospitals classified as significantly better than expected had fewer deaths than expected and a lower p-value less than 0.01. Hospitals classified as significantly worse than expected had more deaths than expected and an upper p-value less than 0.01.

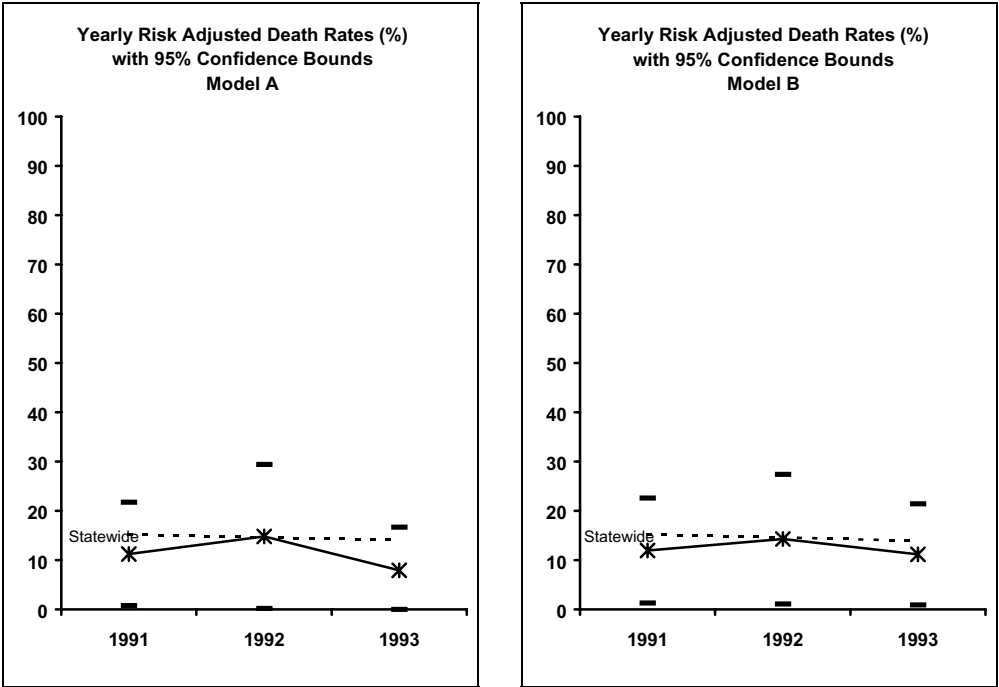

Summarizing the contents of Table 1, General Hospital has an overall risk-adjusted death rate of 10.4 percent from Model A and 12.2 percent from Model B. These rates are less than the overall statewide death rates but these differences are not statistically significant. In the first table in the *Users*

Guide, General Hospital would have been represented by a simple box (□) for Model A and Model B in the results columns.

The Charts, an Example

Table 1 gave the detailed statistics for the fictional General Hospital in Healthy County. Figure 1 below displays General Hospital’s yearly risk-adjusted death rates and the 95 percent confidence bounds around those rates.

Figure 1: Healthy County: General Hospital

Each table for a specific hospital or county is followed by two charts which graphically display the hospital’s or county’s risk-adjusted death rates from Model A and Model B, by year. The risk-adjusted death rates and 95 percent confidence bounds displayed in these charts are identical to those shown in the table on the same page.

The *Users Guide* includes a very similar display of hospitals' risk-adjusted death rates. However, the charts show overall results for 1991-1993 and feature 98 percent rather than 95 percent confidence bounds.

In the charts in this volume, annual risk-adjusted death rates for AMI patients are denoted by asterisks. As described above, the risk-adjusted death rate represents a measure of hospital performance adjusted for differences in patients' severity of illness across hospitals. Each risk-adjusted death rate is surrounded by 95 percent confidence bounds, which are denoted by thick dashes above and below each asterisk. There is a 95 percent chance that a hospital's true risk-adjusted death rate lies within the indicated range.<sup>1</sup>

The statewide death rate is denoted by a horizontal dotted line. Note that the statewide death rate dropped slightly from 15.1 percent in 1991 to 14.5 percent in 1992 to 13.9 percent in 1993. If the horizontal dotted line is below the hospital's lower confidence bound, then that hospital had a significantly higher than average risk-adjusted death rate, and significantly more deaths than were expected, in that year. If the statewide death rate lies above a hospital's upper confidence bound, then that hospital had a significantly lower than average risk-adjusted death rate, and significantly fewer deaths than were expected, in that year. For most hospitals, the statewide rate lies within the confidence bounds, indicating that the hospital's performance was within the expected range. This expected range is substantially wider when individual years are shown separately than when all three years are aggregated, as in the chart in the *Users Guide*.

Because two separate risk-adjustment models were developed to estimate the probability of death, the risk-adjusted death rate and confidence bounds from Model B are displayed next to the comparable data from Model A. If a specific hospital appears to have no point on the chart for one or more years, then that hospital either had no eligible cases or was excluded because of data limitations during that year or set of years. Volume Two, *Technical Guide*, Chapter Six explains which hospitals were excluded because of data limitations. If a hospital had no eligible cases across all three years (1991-1993), then it is not listed in this volume.

1. The confidence bounds shown in these charts are based on a widely used method called the normal approximation (see the *Technical Guide*, Chapter Twelve). For most hospitals, this procedure generated confidence bounds nearly identical to those implied by the exact method that was used to calculate p-values in the detailed statistical tables and to identify mortality outliers in the *Users Guide*. However, a few hospitals have 95 percent confidence bounds that do not include the statewide average, despite the fact that their exact p-value exceeds 0.025. The exact p-value is a more precise measure of the probability that a hospital's true risk-adjusted death rate equals the statewide average.

## Section

# 3

## How Not to Use These Results

*One might be tempted to use this set of hospital data tables to generate lists of the "best and worst" hospitals in the state or in a particular community. This is **not** appropriate. Such listings or rankings are subject to substantial misinterpretation, stemming largely from the problem of chance variability discussed previously. This section discusses how to interpret the observed and expected death rates, and explains why ranking is inappropriate.*

### Interpreting Death Rates

TABLE 2: AMI Data for a Hypothetical Community

Hospital	Cases	Deaths			Death Rate (%)		P-Value	Observed/Expected	Risk Adjusted Rate		
		Observed	Expected	Standard Deviation	Observed	Expected			Observed	Confidence Bound	
										Low	High
A	7	0	1.2	0.85	0.0	17.1	0.184	0.00	0.0	0.0	20.1
B	25	0	3.5	1.69	0.0	14.0	0.019	0.00	0.0	0.0	13.7
C	69	4	8.7	2.50	5.8	12.6	0.037	0.46	6.7	0.0	14.8
D	98	11	16.5	3.43	11.2	16.8	0.068	0.67	9.7	3.8	15.6
E	420	44	66.0	7.01	10.5	15.7	0.001	0.67	9.7	6.6	12.7
F	282	35	45.6	5.74	12.4	16.2	0.037	0.77	11.1	7.5	14.7
G	116	13	14.2	3.34	11.2	12.2	0.434	0.92	13.3	6.6	19.9
H	98	17	13.6	3.21	17.3	13.9	0.182	1.25	18.1	11.4	24.8
I	29	9	5.8	2.01	31.0	20.0	0.093	1.55	22.5	12.6	32.3
County Total	1,144	133	175.1	11.37	11.6	15.3	Z-score = -3.66				

The importance of statistical variability is highlighted by the confidence intervals associated with the risk-adjusted death rates reported for each hospital. To illustrate this, Table 2 presents real AMI data for nine hospitals from across the state, selected to represent a hypothetical community. The hospitals have been ordered from low to high according to their risk-adjusted death rates, using all three years of data combined. The risk-adjusted death rates range from 0 percent to 22.5 percent. The risk-adjusted death rate represents what a hospital's death rate would have been, if its patients' risk profile had been equal to the statewide average.

Hospitals A and B appear at the top of the list because they had no deaths. However, this cannot be interpreted to mean that they had the best outcomes for heart attack patients. Hospital A had only 7 AMI cases, a very small number for statistical inference. The expected number of deaths at this hospital was 1.2. While the observed number of deaths was less than the expected number, this result could be due to chance alone and is not

statistically significant. This is shown by the p-value of 0.184, which indicates that with such a small number of cases, one would expect to observe zero deaths 18.4 percent of the time just by chance.

The absence of any deaths among the 25 patients at Hospital B is more unusual. The expected number of deaths was 3.5, and the p-value indicates that one would expect to observe zero deaths only 1.9 percent of the time, if there were many identical hospitals. With 418 hospitals in the state included in the heart attack analysis, chance alone would account for 8 hospitals (1.9 percent times 418 = 7.9) having such extreme values just by chance.

In the *Users Guide*, both Hospital A and Hospital B would be labeled with a check mark in a box (☑). Neither hospital was significantly different than expected at a p-value of 0.01, but neither had any deaths.

Note that Hospital E, which ranks 5th in this community in terms of risk-adjusted rates, is the only one that would be labeled with a star (★) in the *Users Guide*, as indicated by its lower p-value of 0.001. This illustrates the importance of sample size in determining statistical significance. Hospitals with relatively few patients cannot be identified as having significantly better than expected results, even with very few (or no) deaths, because such results may be due to chance.

At the other extreme of the table are Hospitals H and I with risk-adjusted death rates of 18.1 percent and 22.5 percent respectively. The very high death rate at Hospital I was based on 9 deaths among 29 patients, almost the opposite situation as Hospital B. The observed rate was more than 50 percent higher than the expected rate (31.0 percent vs. 20.0 percent). Even so, a result this extreme or worse is likely to occur just by chance about 9 times out of a hundred, as indicated by the p-value of 0.093. Even using the standard cut-off for a p-value of 0.05 or less, this is not a statistically significant result.

## Why Ranking is Inappropriate

The dangers of ranking hospitals are illustrated by the lower and upper confidence bounds around each hospital's risk-adjusted death rate. These represent the bounds within which the true risk-adjusted rate would be expected to lie, given the role of chance and the observed rate. For example, Hospital B's true risk-adjusted rate might have been as high as 13.7 percent despite having zero deaths. If this were the case, Hospital B would rank seventh out of the nine hospitals in this community, instead of first or second. Even if everything remained the same in terms of the quality of care, numbers of patients, and average risk among these hospitals, a change in ranking this large could be observed just due to chance variation. Likewise, Hospital I, with the highest risk-adjusted death rate, could have a rate as low as 12.6 percent, which would rank it seventh in this community.

Potential problems in using rankings are exacerbated if one considers rankings based on the entire state. For the purposes of illustration, the nine hospitals in Table 2 were selected largely from the extremes of the death rate distribution. In fact, the vast majority of hospitals are in the middle of that distribution. For example, Hospital A is among dozens that would rank "first in the state" because it had no deaths, yet Hospital G, which is near the middle in the overall list, might rank just as highly based on the lower confidence bound for its risk-adjusted rate. At the other extreme, the lower bound on the confidence interval for Hospital I, 12.6 percent, would rank it in the top quarter of hospitals in the state. In fact, because there are so many hospitals in the state and the confidence intervals are so wide, the range of possible ranks for many hospitals, due to chance alone, exceeds 100.

This example is meant to caution potential users of the data about the basic statistical issues involved in using such information. It is important to note that unusual events do happen by chance, so that a single set of results provides little information. However, if "unusual" results occur repeatedly, they may bear further investigation. Thus, hospitals with "extreme" results three years in a row are likely to have some consistent factors producing those results.

## How These Data Might Be Used

---

*It is important to recall that most statistical problems in interpreting these data arise when one focuses on death rates, because deaths are relatively unusual occurrences. Some other analyses would be less susceptible to chance variation and potentially more informative.*

### Examine Individual Hospitals

For example, one may ask whether special circumstances accounted for the very small number of AMI patients at Hospital A. With roughly one admission every other month, staff may not be ready for such emergency admissions. If Hospital A is in a very isolated area and is the only local provider, this low volume may be quite appropriate. The high expected death rates in Hospital A suggest that Hospital A's patients may be too high-risk to transfer elsewhere.

Another suggestion would be to examine hospitals with unusually low or high expected death rates. A hospital's expected death rate is a measure of the average severity-of-illness of its patients, compared with patients at other hospitals and statewide. Hospitals with low expected death rates may be referring high-risk patients from their emergency departments to other hospitals with more specialized facilities. In most areas, that would represent an appropriate referral practice. Alternatively, they may be failing to report some of their patient's risk factors. Hospitals with high expected death rates may be located near a retirement community or other high-risk population, may accept especially high-risk patients from other hospitals, or may over-report risk factors relative to other hospitals.

### Examine Groups of Hospitals

One might also combine results for hospitals grouped in various ways. Grouping adds to the sample size and thus reduces the role of chance variation in explaining unusual outcomes. However, the grouping should be related to important underlying characteristics, such as the size of a hospital or its location. Hospitals also might be grouped according to health plan affiliations in a managed care environment. For readers' convenience, this volume includes a summary table for each county, which groups all of the hospitals in that county.

To illustrate grouping, consider the bottom part of Table 2, where the outcomes for all nine hospitals in a hypothetical community are aggregated. There were a total of 133 deaths among the 1,144 patients, while 175.1 were

expected given their risk factors. This results in an overall death rate of 11.6 percent, compared to an expected rate of 15.3 percent. If the number of expected deaths is 5 or more, one can use the following formula to determine whether this is a statistically significant difference:

$$Z = I * (ABS(NDEAD - NEXP) - 0.5) / STDDEV$$

where  $I = (NDEAD - NEXP) / ABS (NDEAD - NEXP)$

where NDEAD is the number of patients who died, NEXP is the number of patients expected to die, and STDDEV is the standard deviation around the observed number of deaths for the group of interest, in this case a hypothetical community. The detailed statistical tables list this standard deviation for each model and each hospital. To calculate the standard deviation for a group of hospitals, square the standard deviation for each hospital in the group (using either Model A or Model B). Then add the resulting variances. Finally, take the square root of the sum of the variances to obtain the standard deviation of the observed number of deaths for the entire group of hospitals.

The resulting figure, or Z-score, can be converted to a probability with the assistance of standard statistical tables for the normal distribution. Roughly speaking, Z-score values greater than 1.96 or less than -1.96 indicate that a result is statistically significant at the 0.05 level. This means these results are likely to occur by chance less than one time out of 20. The resulting Z-score for this set of 9 hospitals is 3.66, with a negative value indicating that the death rate was lower than expected. Standard statistical tables for the normal distribution indicate that a Z-score of 3.66 is associated with a probability of less than 0.001. Results this extreme are likely to occur by chance less than one out of a thousand times. Thus, overall outcomes in this community were significantly better than expected, even though two hospitals in this group had worse than expected outcomes.

## Diskette Record Layout

*There are four files on the diskette, one for each of the individual years, and one for all three years together. The layout of each file is the same.*

COLUMN	COLUMN HEADING	DESCRIPTION
A	OSHPDID	Hospital's OSHPD ID Number
B	HOSPNAME	Hospital's Name
C	STAPER_A	Statewide Mortality Rate, Model A
D	STAPER_B	Statewide Mortality Rate, Model B
E	NUMCAS_A	Number of Cases Included, Model A
F	NUMCAS_B	Number of Cases Included, Model B
G	NUMMOR_A	Number of Observed Deaths, Model A
H	NUMMOR_B	Number of Observed Deaths, Model B
